

Python - pass Statement

Python pass Statement

Python **pass statement** is used when a statement is required syntactically but you do not want any command or code to execute. It is a null which means nothing happens when it executes. This is also useful in places where piece of code will be added later, but a placeholder is required to ensure the program runs without errors.

For instance, in a function or class definition where the implementation is yet to be written, **pass statement** can be used to avoid the **SyntaxError**. Additionally, it can also serve as a placeholder in control flow statements like for and while loops.

Syntax of pass Statement

Following is the syntax of Python **pass statement** –

```
pass
```

Example of pass Statement

The following code shows how you can use the **pass statement** in Python –

```
for letter in 'Python':  
    if letter == 'h':  
        pass  
        print ('This is pass block')  
    print ('Current Letter :', letter)  
print ("Good bye!")
```

When the above code is executed, it produces the following **output** –

```
Current Letter : P
Current Letter : y
Current Letter : t
This is pass block
Current Letter : h
Current Letter : o
Current Letter : n
Good bye!
```

Dumpy Infinite Loop with pass Statement

This is simple enough to create an infinite **loop** using **pass statement** in Python.

Example

If you want to code an infinite loop that does nothing each time through, do it as shown below –

```
while True: pass
# Type Ctrl-C to stop
```

Because the body of the loop is just an empty statement, Python gets stuck in this loop.

Using Ellipses (...) as pass Statement Alternative

Python 3.X allows **ellipses** (coded as three consecutive dots ...) to be used in place of **pass statement**. Both serve as placeholders for code that are going to be written later.

Example

For example if we **create a function** which does not do anything especially for code to be filled in later, then we can make use of ...

```
def func1():
    # Alternative to pass
    ...

# Works on same line too
def func2(): ...
```

```
# Does nothing if called  
func1()  
func2()
```
