

Python - String Concatenation

Concatenate Strings in Python

String concatenation in Python is the operation of joining two or more strings together. The result of this operation will be a new string that contains the original strings. The diagram below shows a general string concatenation operation –

In Python, there are numerous ways to concatenate strings. We are going to discuss the following –

- Using '+' operator
- Concatenating String with space
- Using multiplication operator
- Using '+' and '*' operators together

String Concatenation using '+' operator

The "+" operator is well-known as an addition operator, returning the sum of two numbers. However, the "+" symbol acts as string **concatenation operator** in **Python**. It works with two string operands, and results in the concatenation of the two.

The characters of the **string** on the right of plus symbol are appended to the string on its left. Result of concatenation is a new string.

Example

The following example shows string concatenation operation in Python using + operator.

```
str1="Hello"
str2="World"
print ("String 1:",str1)
print ("String 2:",str2)
str3=str1+str2
print("String 3:",str3)
```

It will produce the following **output** –

```
String 1: Hello
String 2: World
String 3: HelloWorld
```

Concatenating String with space

To insert a whitespace between two strings, we can use a third empty string.

Example

In the below example, we are inserting space between two strings while concatenation.

```
str1="Hello"
str2="World"
blank=" "
print ("String 1:",str1)
print ("String 2:",str2)
str3=str1+blank+str2
print("String 3:",str3)
```

It will produce the following **output** –

```
String 1: Hello  
String 2: World  
String 3: Hello World
```

String Concatenation By Multiplying

Another symbol `*`, which we normally use for multiplication of two numbers, can also be used with string operands. Here, `*` acts as a repetition operator in Python. One of the operands must be an integer, and the second a string. The integer operand specifies the number of copies of the string operand to be concatenated.

Example

In this example, the `*` operator concatenates multiple copies of the string.

```
newString = "Hello" * 3  
print(newString)
```

The above code will produce the following **output** –

```
HelloHelloHello
```

String Concatenation With '+' and '*' Operators

Both the repetition operator (`*`) and the concatenation operator (`+`), can be used in a single expression to concatenate strings. The `"*"` operator has a higher precedence over the `"+"` operator.

Example

In the below example, we are concatenating strings using the `+` and `*` operator together.

```
str1="Hello"  
str2="World"  
print ("String 1:",str1)  
print ("String 2:",str2)
```

```
str3=str1+str2*3
print("String 3:",str3)
str4=(str1+str2)*3
print ("String 4:", str4)
```

To form **str3** string, Python concatenates 3 copies of World first, and then appends the result to Hello

```
String 3: HelloWorldWorldWorld
```

In the second case, the strings str1 and str2 are inside parentheses, hence their concatenation takes place first. Its result is then replicated three times.

```
String 4: HelloWorldHelloWorldHelloWorld
```

Apart from + and *, no other arithmetic operators can be used with string operands.
